Lab Instructor: Kevin Stroski

#### **Abstract**

Gas chromatography with a mass spectrometer was utilized for analysis.

# 1 Introduction

Gas chromatography (GC) is a separation technique that analyzes volatile compounds [1]. Consequently, this analysis can lead a lot of useful situations such as the determination of the purity of a compound or even detecting explosives [1]. In GC, the analyte is volatilized and carried through the column by the mobile phase, often called the carrier gas [2]. This carrier gas can either be He or H<sub>2</sub> [2]. These gases are often chosen as the carrier gas as they are chemically inert and would therefore not react with the analytes [1].

Polybrominated diphenyl ethers (PBDEs) are a class of halogenated compounds that are commonly used as flame retardants [3]. These compounds are an environmental health hazard as they have the potential to accumulate in the food chain [4]. In addition, BDE-47, a PBDE congener, has been found to cause neurotoxic effects in adults [4]. Commonly used detection techniques for PBDEs are high-resolution mass spectrometry and low-resolution mass spectrometry (LRMS) [3]. LRMS is commonly done with selected ion monitoring (SIM) [3]. SIM increases the selectivity of mass spectrometry for analytes and reduces its response to everything else [2].

The main objective of this experiment is to make a method that uses a SIM for quantitative analysis of PBDEs by GC-EI-LRMS.

## 2 Chemicals, Methods and Instrumentation

### 2.1 Chemicals

In the first week, BDE-47, PBB-77 and '2-HCH, all of each were at a concentration of 50  $\mu\text{g}/\text{mL}$  in isooctane, were used as standard solutions. In the second week, fish oil (Exact Norwegian Cod Liver Oil), dichloromethane (emd, Lot 5Q160, CAS: 75-09-2) and PBB-77, at a concentration of 10  $\mu\text{g}/\text{mL}$  in isooctane, were used as chemicals. Finally, in the last week, BDE-47, PBB-77 and '2-HCH, each at a concentration of 10  $\mu\text{g}/\text{mL}$  in isooctane, were used. Throughout the entirety of the experiment, hexane (Caledon Laboratory Chemicals, CAS no. 110-54-3, LOT: 89001) and isooctane (OmniSolv, CAS: 540-84-1, LOT: 52054) were used.

### 2.2 Instrumentation

The separation and analysis of the entire experiment was performed on an Agilent 7890A GC, coupled with a 5975C inert XL EI/CI MSD with a triple axis detector. The dimensions of the column used was  $30\text{m} \times 0.250\text{mm} \times 0.25\mu\text{m}$ , by Agilent Technologies. The stationary phase was (5%-Phenyl)-methylpolysiloxane. Each analysis was performed with the injection mode at splitless, with He as the carrier gas, and the flow rate was set at 1 mL/min. Do I need to state the pressure and volume and splitless?

## 2.3 Methods

# 3 Results and Discussion

## 3.1 Results

Table 1 shows some cool stuff, and table 2 shows the molecular weight of BDE-47, PBB-77 and '2-HCH.

Table 1: Selected Ion Monitoring Parameters

Compound	Ions monitored (m/z)	Time window (min)
'2-HCH	181, 219	0.5 - 19
BDE-47	326, 486	19 - 22.5
PBB-77	470, 310	22.5 - 24

Table 2: Molecular weight of BDE-47, PBB-77 and '2-HCH

Compound	Molecular weight (amu)
BDE-47	486
PBB-77	470
'2-HCH	291

## 3.2 Discussion

## 5 Appendix

### 5.1 Calculations

Calculating the capacity factor of chlorobenzene for figure 2 of the chromatogram

$$\begin{aligned}K &= \frac{t_r - t_m}{t_m} \\K &= \frac{2.343 - 1.438}{1.438} \\K &= \frac{0.905}{1.438} \\K &= 0.629346 \approx 0.629\end{aligned}\tag{1}$$

Equation 1 was taken from [2].

### 5.2 Chromatograms

There are ? sheets of GC-MS chromatograms.
